THREE-DIMENSIONAL CONTACT-SENSITIVE FEATURE FOR ELECTRONIC DEVICES

FIELD OF THE INVENTION

5 The present invention relates to input mechanisms for electronic devices. In particular, the present invention relates to contact-sensitive input features for electronic devices.

BACKGROUND OF THE INVENTION

10 Typical input mechanisms for electronic devices and computers include button mechanisms and mechanical actuation switches. These input mechanisms can be subject to failure through repeated use. They require multiple components that can move relative to one another, and may require hinges, springs or joints that are subject to fatigue.

15 Another type of input mechanism is a digitizer. The digitizer can detect contact on a surface that is typically incorporated with a display. The digitizer may be a component of small computing devices, such as handheld computers, or personal digital assistants (PDAs). An assembly of the digitizer assigns identifying voltage values for different contact points distributed across the digitizer's surface. This allows the user to distinguish a communication by positioning an external object on a specific position of the digitizer.

20 Inputs such as gestures, taps, and drags are made on the surface of the digitizer through contact. Icons or other visual cues may be employed with the digitizer to give a user an indication that contact with a specific position on the digitizer will cause a processor of the device to perform a specific function. Digitizers are relatively planar, so that contact points on the surface of the digitizer are positions on the same plane. When users enter input
25 through a digitizer, the user selects planar positions on the digitizer's surface for contact with the external object.

FIG. 10 is an illustration of a prior art display module 900. The display module 900 is contact-sensitive to produce electrical signals in response to contact. The electrical signals are subsequently converted to input. The display module 900 includes an exterior layer 910, a conductive layer 920, a substrate 930 and a display 940. The exterior layer 910 is a polyester (PET) film. The conductive layer 920 comprises a first conductive film 922, an air gap 926 formed by spacers 945, and a second conductive film 924. The conductive films 922, 924 are formed of Indium Tin Oxide material, which has a paste constituency. The spacers 945 are formed from glass or plastic. The substrate 930 is also formed from glass or plastic. The layers formed above display 940 provide a digitizer for the device. The combination of layers for the digitizer is clear to enable viewing of an image created by display 940.

Mechanical buttons are sometimes preferred for certain functions because they provide a better tactile feedback for the function being requested by the input. For example, navigation buttons for scrolling a display of a handheld computer are often mechanical buttons, because they provide a better feel of movement being created when scrolling the display.

1994 1995 1996 1997 1998 1999 2000 2001 2002 2003 2004 2005 2006 2007 2008 2009 2010 2011 2012 2013 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2026 2027 2028 2029 2030 2031 2032 2033 2034 2035 2036 2037 2038 2039 2040 2041 2042 2043 2044 2045 2046 2047 2048 2049 2050 2051 2052 2053 2054 2055 2056 2057 2058 2059 2060 2061 2062 2063 2064 2065 2066 2067 2068 2069 2070 2071 2072 2073 2074 2075 2076 2077 2078 2079 2080 2081 2082 2083 2084 2085 2086 2087 2088 2089 2090 2091 2092 2093 2094 2095 2096 2097 2098 2099 2100 2101 2102 2103 2104 2105 2106 2107 2108 2109 2110 2111 2112 2113 2114 2115 2116 2117 2118 2119 2120 2121 2122 2123 2124 2125 2126 2127 2128 2129 2130 2131 2132 2133 2134 2135 2136 2137 2138 2139 2140 2141 2142 2143 2144 2145 2146 2147 2148 2149 2150 2151 2152 2153 2154 2155 2156 2157 2158 2159 2160 2161 2162 2163 2164 2165 2166 2167 2168 2169 2170 2171 2172 2173 2174 2175 2176 2177 2178 2179 2180 2181 2182 2183 2184 2185 2186 2187 2188 2189 2190 2191 2192 2193 2194 2195 2196 2197 2198 2199 2200 2201 2202 2203 2204 2205 2206 2207 2208 2209 2210 2211 2212 2213 2214 2215 2216 2217 2218 2219 2220 2221 2222 2223 2224 2225 2226 2227 2228 2229 2230 2231 2232 2233 2234 2235 2236 2237 2238 2239 2240 2241 2242 2243 2244 2245 2246 2247 2248 2249 2250 2251 2252 2253 2254 2255 2256 2257 2258 2259 2260 2261 2262 2263 2264 2265 2266 2267 2268 2269 2270 2271 2272 2273 2274 2275 2276 2277 2278 2279 2280 2281 2282 2283 2284 2285 2286 2287 2288 2289 2290 2291 2292 2293 2294 2295 2296 2297 2298 2299 2300 2301 2302 2303 2304 2305 2306 2307 2308 2309 2310 2311 2312 2313 2314 2315 2316 2317 2318 2319 2320 2321 2322 2323 2324 2325 2326 2327 2328 2329 2330 2331 2332 2333 2334 2335 2336 2337 2338 2339 2340 2341 2342 2343 2344 2345 2346 2347 2348 2349 2350 2351 2352 2353 2354 2355 2356 2357 2358 2359 2360 2361 2362 2363 2364 2365 2366 2367 2368 2369 2370 2371 2372 2373 2374 2375 2376 2377 2378 2379 2380 2381 2382 2383 2384 2385 2386 2387 2388 2389 2390 2391 2392 2393 2394 2395 2396 2397 2398 2399 2400 2401 2402 2403 2404 2405 2406 2407 2408 2409 2410 2411 2412 2413 2414 2415 2416 2417 2418 2419 2420 2421 2422 2423 2424 2425 2426 2427 2428 2429 2430 2431 2432 2433 2434 2435 2436 2437 2438 2439 2440 2441 2442 2443 2444 2445 2446 2447 2448 2449 2450 2451 2452 2453 2454 2455 2456 2457 2458 2459 2460 2461 2462 2463 2464 2465 2466 2467 2468 2469 2470 2471 2472 2473 2474 2475 2476 2477 2478 2479 2480 2481 2482 2483 2484 2485 2486 2487 2488 2489 2490 2491 2492 2493 2494 2495 2496 2497 2498 2499 2500 2501 2502 2503 2504 2505 2506 2507 2508 2509 2510 2511 2512 2513 2514 2515 2516 2517 2518 2519 2520 2521 2522 2523 2524 2525 2526 2527 2528 2529 2530 2531 2532 2533 2534 2535 2536 2537 2538 2539 2540 2541 2542 2543 2544 2545 2546 2547 2548 2549 2550 2551 2552 2553 2554 2555 2556 2557 2558 2559 2560 2561 2562 2563 2564 2565 2566 2567 2568 2569 2570 2571 2572 2573 2574 2575 2576 2577 2578 2579 2580 2581 2582 2583 2584 2585 2586 2587 2588 2589 2590 2591 2592 2593 2594 2595 2596 2597 2598 2599 2600 2601 2602 2603 2604 2605 2606 2607 2608 2609 2610 2611 2612 2613 2614 2615 2616 2617 2618 2619 2620 2621 2622 2623 2624 2625 2626 2627 2628 2629 2630 2631 2632 2633 2634 2635 2636 2637 2638 2639 2640 2641 2642 2643 2644 2645 2646 2647 2648 2649 2650 2651 2652 2653 2654 2655 2656 2657 2658 2659 2660 2661 2662 2663 2664 2665 2666 2667 2668 2669 2670 2671 2672 2673 2674 2675 2676 2677 2678 2679 2680 2681 2682 2683 2684 2685 2686 2687 2688 2689 2690 2691 2692 2693 2694 2695 2696 2697 2698 2699 2700 2701 2702 2703 2704 2705 2706 2707 2708 2709 2710 2711 2712 2713 2714 2715 2716 2717 2718 2719 2720 2721 2722 2723 2724 2725 2726 2727 2728 2729 2730 2731 2732 2733 2734 2735 2736 2737 2738 2739 2740 2741 2742 2743 2744 2745 2746 2747 2748 2749 2750 2751 2752 2753 2754 2755 2756 2757 2758 2759 2760 2761 2762 2763 2764 2765 2766 2767 2768 2769 2770 2771 2772 2773 2774 2775 2776 2777 2778 2779 2780 2781 2782 2783 2784 2785 2786 2787 2788 2789 2790 2791 2792 2793 2794 2795 2796 2797 2798 2799 2800 2801 2802 2803 2804 2805 2806 2807 2808 2809 2810 2811 2812

5 mechanically combined components, making it more resilient than other input mechanisms.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments of the invention are illustrated by way of example, and not by way of limitation, in the figures of the accompanying drawings. Like reference numerals are intended to refer to similar elements among different figures.

5 FIG. 1 is an exploded, isometric view of an electronic device including a contact-sensitive surface feature, under an embodiment of the invention.

FIG. 2A is a cross-sectional view of a length of the electronic device's housing, cut along lines A-A of FIG. 1, under an embodiment of the invention.

10 FIG. 2B is a cross-sectional view of a length of the electronic device's housing, under another embodiment of the invention.

FIG. 2C is a cross-sectional view of a length of the electronic device's housing, under another embodiment of the invention.

FIG. 3 is a close-up view of a recess shown by line C in FIG. 2A, under an embodiment of the invention.

15 FIG. 4 is a close-up view of another type of surface feature combination for use with an electronic device, under an embodiment of the invention.

FIG. 5 is a close-up view of another type of surface feature combination for use with an electronic device, under an embodiment of the invention.

20 FIG. 6 is a close-up view of another type of surface feature combination for use with an electronic device, under an embodiment of the invention.

FIG. 7 is a cross-sectional view of a length of the electronic device's housing, the housing including a protruding contact-sensitive surface feature, under another embodiment of the invention.

25 FIG. 8 is a cross-sectional view of a length of the electronic device's housing, the housing including a surface mounted feature for entering input, under another embodiment of the invention.

FIG. 9 is a hardware diagram of an electronic device, under an embodiment of the invention.

FIG. 10 is a prior art illustration of a display module including a digitizer.

DETAILED DESCRIPTION OF THE INVENTION

Embodiments of the invention describe three-dimensional contact-sensitive input mechanisms for electronic devices. In the following description, for the purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of the present invention. It will be apparent, however, that the present invention may be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form in order to avoid unnecessarily obscuring the present invention.

A. Overview

Embodiments of the invention provide an input mechanism for an electronic device. The input mechanism is a shaped feature combined with a contact-sensitive material. The input mechanism may be integrated with a display module or housing of the electronic device.

Under an embodiment of the invention, an electronic device is formed at least partially from a deflectable material that generates an electrical signal in response to contact. The first material is integrated with a portion of the electronic device to provide a shaped feature on an exterior surface of the housing and/or display module. The shaped feature detects contact with an external object on one or more contact points. The contact points correspond to regions where contact is interpreted as a defined input that is signaled for a processor of the electronic device.

In an embodiment, the deflectable material with the shaped feature may be an integrated or unitary function of a display module for the electronic device. Alternatively, the deflectable material and shaped feature can be included with the housing.

In an embodiment, the contact-sensitive feature may be unitarily formed with a housing of the electronic device. The housing of the electronic device may also be combined with a display module. As used herein, unitarily formed means that the components are combined in a manufacturing process to be one component or item for the end user. The components may be combined on a molecular level in order to be unitarily formed.

B. Electronic Device With Contact-Sensitive Surface Feature

FIG. 1 illustrates an electronic device 100 equipped with a display module 120, under an embodiment of the invention. The electronic device 100 includes a housing 110 having a front panel 112 to provide a display surface 122 of housing 110. One or more contact-sensitive, three-dimensional features are formed on an exterior surface of the electronic device 100. The front panel 112 extends between a top 102 and a bottom 104, and between opposing lateral sides 105.

In an embodiment, electronic device 100 is a handheld computer, such as a PDA manufactured by Palm Inc, or a device operating a POCKET PC or WINDOWS CE operating system, manufactured by MICROSOFT. In other embodiments, electronic device 100 includes devices such as touch-sensitive computer tablets, laptop computers, mobile phone devices, or any other device containing processing resources.

In an embodiment, housing 110 is formed at least partially from a contact-sensitive material that generates an electrical signal in response to being contacted by an external object. The material is deflectable or otherwise deformable to generate a voltage differential, causing a current to be generated as a signal.

The display module 120 may include components for detecting contacts on display surface 122. As such, display module 120 may be formed from the same contact-sensitive

material used with housing 110. Alternatively, display module 120 is formed from a different type of contact sensitive material. Still further, housing 110 may contain display module 120, with contact-sensitive features being provided only on display surface 122.

5 The electronic device 100 includes a plurality of surface features, provided on front panel 112 and/or display surface 122. The surface features are formed from the contact-sensitive material on the remainder of housing 110. The contact-sensitive material is shaped or molded into a three-dimensional feature provided on a surface of housing 110.

10 In an embodiment, the surface features include a first recess 130 and a pair of second recesses 132. Each recess 130, 132 is formed to detect a contact from an external object, such as a contact mechanism, stylus, finger or other extension. The recesses 130, 132 can be deflected by contact to generate electrical signals that are received as input by electronic device 100.

15 In one configuration, first recess 130 is positioned adjacent to display surface 122, between the display surface and a bottom edge 104 of housing 110. Second recesses 132 are shown between display surface 122 and a lateral side 105 of housing 110. Each recess 130, 132 is actuatable through contact to signal a command for a processor. The recesses 130, 132 may be pre-associated with one or more functions that can be performed by the processor.

20 In an embodiment, second recesses 132 are actuatable as switches. That is, the second recesses 132 may be contacted to cause one signal assertion, similar to the operation of a button. The first recess 130 includes multiple contact points to enable users to create multiple signal assertions from the same relative position. The multiple contact points of recess 130 allow for multiple inputs, where each input is distinguished by the position of the external object contacting the first recess 130. For example, recess 130 may be contacted in a portion

proximate to display surface 122 to cause an image appearing on display surface 122 to scroll upwards. Likewise, recess 130 may be contacted in a position distal to display surface 122 to cause an image appearing on display surface 122 to scroll downwards.

FIG. 1 shows that first recess 130 may be coupled to an optional contact mechanism 140 to facilitate entering contacts. The contact mechanism 140 may be coupled to recess 130 during a manufacturing step, or may be configured to be attachable to one or more of the recesses 130, 132 by an end user. In one embodiment, contact mechanism 140 includes a swivel 144 that can be pivoted within first recess 130. The swivel 144 includes an opening 147 for an end piece 148. The end piece 148 fits into opening 147 to provide an exterior contact surface for swivel 144. Swivel 144 includes a bottom portion 145 that rests in recess 130. The bottom portion 145 is contoured or rounded to enable swivel 144 to rock along an axis X and/or Y. In this way, swivel 144 can be pivoted in at least two directions to generate different input signals from recess 130. When pivoted, swivel 144 may be directed into a contact point of recess 130, so as to cause an input signal to be signaled to the processor of electronic device 100.

In another implementation, contact points are provided on recess 130 so that swivel 144 can be directed in eight directions within contact recess 130. Each contact point may correspond to a different input. This allows swivel 144 and end piece 148 to be operated like a multi-directional joystick.

Portions of electronic device 100 are formed from a conductive, contact-sensitive material that is pliable into to different types of surface features. The contact-sensitive material may be integrated with the housing 110 and/or display module 120. A surface feature shaped by the contact-sensitive may be viewed as a portion of display module 120 if

the surface feature is formed as an integrated extension of display 120, even if the surface feature is provided on a region of the electronic device that is outside the footprint of display surface 122. The surface feature may alternatively be viewed as a portion of housing 110 if the surface feature is formed on a structure that is distinct from display module 120.

5 Therefore, the surface feature is formed on a region of a layer formed from the contact-sensitive material. The layer of contact-sensitive may overlap a portion of the front panel's footprint.

FIG. 2A is a cross-sectional view of display module 120 of handheld computer 100, cut along lines A-A of FIG. 1, under an embodiment of the invention. The display module 10 120 includes a digitizer pad 250 to enable the display module to detect contact. An embodiment incorporates a surface feature on a segment of digitizer pad 250. The digitizer pad 250 includes an exterior layer 222, an intermediate conductive section 224, interior layer 226, and substrate 228. The digitizer pad 250 may be incorporated to form a contact-sensitive portion of housing 110, and/or of display module 120. To this end, digitizer pad 250 may be 15 extended over a region that overlaps display module 120 and portions of front panel 112. Opposing sealing elements 229 form a boundary for the conductive portion of digitizer pad 250.

When incorporated with display module 120, digitizer pad 250 extends over a display 20 230. The display 230 includes pixels or other display elements for creating an image from a processor signal. The layers of display module 120 overlaying display 230 are clear or translucent to enable a user to view the image.

In an embodiment, an exterior layer 222 of the contact-sensitive portion is formed of a PET film. The exterior layer 222 may have a thickness range between 75-180 micrometers.

The exterior layer 222 forms a protective barrier for display module 120, while providing display surface 122 as a smooth area for receiving contact by a stylus tip or other instrument. In an embodiment, segments 117 of front panel 112 are provided over regions of digitizer pad 250 where contact-sensitive input is not wanted, corresponding to where sealing elements 229 are located.

The conductive section 224 includes a first conductive layer 221, an air gap 223 and a second conductive layer 227. The first and second conductive layers 221 and 227 are formed of a material having a property of generating an electrical signal when made to contact one another. A plurality of spacers 225 define air gap 223. The first conductive layer 221 may be deflected into air gap 223 to make contact with second conductive layer 227. When first conductive layer 221 is made to contact second conductive layer 227, a signal is generated for the processor of electronic device 100. The signal may be differentiable to indicate a position where the first conductive layer 221 is made to contact the second conductive layer 227.

In an embodiment, the conductive layers 221 and 227 are each formed by a PET layer combined with a conductive paste. The conductive paste is clear or translucent, and can be formed into a three-dimensional shape during a manufacturing process. At least the first conductive layer 221 is deformable to extend across air gap 223 and make contact with second conductive layer 227, resulting in a voltage signal that is later interpreted as processor signals. Opposing sealing components 229 form a boundary for conductive section 224. The spacers 225 may be formed from glass or clear plastic. In one implementation, the conductive paste for conductive layers 221 and 227 is a clear paste commercially available under the trade name ELECTRODAG, manufactured by ACHESON. This material also has

the property of being pliable for creating shapes and other features. NISSHA of Japan manufactures a film product for conductive layers 221 and 227, using ELECTRODAG.

A thickness of conductive section 224 for each conductive layer 221 and 227 ranges between 150-220 micrometers, and preferably at about 180-200 micrometers. The thickness
5 for air gap 223 may range between 200-400 micrometers, and corresponds to a diameter of spacers 225.

As an alternative, conductive section 224 may be formed of Indium Tin Oxide. The spacer balls 225 may be distributed within conductive section 224 to create a support structure for a three-dimensional feature.

10 The interior layer 226 is optional. The interior layer 226 may be formed from a PET material similar to exterior layer 222. The conductive section 224 can generate a differentiable voltage signal for substrate 228 when first conductive layer 221 is made to contact second conductive layer 227. The substrate 228 includes traces and other electronic contacts that signal voltage differentials generated from conductive section 224 to a
15 component such as an analog-digital converter. The AD converter converts the voltage differential signal to a digital format for the processor of the electronic device.

In an embodiment, a footprint of display 230 is smaller than a footprint of the other layers of display module 120. As described with FIG. 1, the conductive section 224 of display module 120 may extend across a majority of front panel 112 (FIG. 1).

20 The surface feature creates a variable thickness in digitizer pad 250. This may correspond to a region of housing 110 and/or display module 120. When the surface feature is employed on front panel 112 (or other housing surface), the front panel 112 may include

impression or shape of variable thickness corresponding to the surface feature. The exterior layer 222 one or more contact points for digitizer 250.

In one embodiment, the layers forming digitizer pad 250 are contoured or shaped with the impression on the exterior surface. FIG. 2A shows that first conductive layer 221, second conductive layer 227, and interior layer 226 may be contoured or indented inward (or outward). The substrate 228 may also be contoured. Therefore, multiple layers of the contact-sensitive portion, including first conductive layer 221 and second conductive layer 227, are contoured to match the shape of recess 130.

FIG. 2B illustrates an embodiment where only the exterior layer 222 and the first conductive layer 221 are contoured to provide recess 130. The second conductive layer 227 is planar with substrate 228. The air gap 223 therefore narrows between the first and second conductive layers 221 and 227. The narrow region of air gap 223 may be used to provide a feature that is more sensitive to contact.

In an embodiment shown by FIGS. 2A and 2B, recess 130 is formed on a portion of display module 120 that extends beyond the footprint of display 230. The recess 130 may be formed to appear as either a portion of housing 110 or as a feature of display module 120.

FIG. 2C illustrates another configuration where recess 130 is formed on a portion of front panel 112 separated from display surface 122 through surface housing segments 117. In this configuration, recess 130 forms a portion of the housing 110 (FIG. 1) for electronic device 100. A rigid layer such as provided by housing segments 117 precludes first conductive layer 221 from being deformed to make contact with second conductive layer 227.

Alternatively, the front panel 112 may include recess 130 and be isotropic with display module 120, so that the front panel and display surface 122 are relatively seamless. The spacers 245 of air gap 223 may be configured to preclude first conductive layer 221 from contacting second conductive layer 227 in that localized region. Thus, the contact required for entering input through the digitizer portion of the housing may be localized to the region of recess 130.

In another embodiment, recess 130 forms a portion of the display surface 122 (FIG. 1) that is inoperative. Still further, another embodiment may provide that recess 130 is formed onto an active portion of display surface 122, within the footprint of display 230.

C. Configurations and Mechanisms For Contact-Sensitive Surface Feature

FIG. 3 is a close-up view of recess 130, under an embodiment of the invention. The recess 130 is shaped to be coupled with contact mechanism 140 (FIG. 1). The exterior layer 222, first conductive layer 221, second conductive layer 227, and interior layer 226 are all contoured to define a shape for recess 130. The substrate 228 (FIGS. 2A and 2B) may also be shaped for recess 130. The first and second conductive layers 221 and 227 are formed from a pliable material that can be shaped to define recess 130, or another feature. One or more contact points may be included on recess 130 to define where first conductive layer 221 may be combined with second conductive layer 227 to signal the processor of the electronic device 100.

According to embodiment, a first contact point 232 is disposed towards bottom 104 of housing 110 (FIG. 1), and a second contact point 234 is disposed towards top 102 of housing 110 (FIG. 1). Each contact point 232, 234 is a region or segment of the shaped feature aligned or otherwise coupled to an electrical lead for detecting a voltage differential

generated in that region from contact. Additional contact points may be similarly provided on recess 130. The swivel 144 of contact mechanism 140 pivots within recess 130 to make contact with contact points 232 and 234. Alternatively, other external objects such as stylus tips and fingers may be used to make contact with contact points 232 and 234.

5 FIG. 4 illustrates another embodiment where a gel cap 330 is positioned within recess 130 to facilitate a user in actuating the contact points 232, 234. The gel cap 330 is fixed to recess 130 at bottom position 335. Adhesives or other fasteners may be used to fix gel cap 330. The mass within gel cap 330 can be moved within recess 130 through contact. When moved, the shape of gel cap 330 can be deformed to apply sufficient pressure for effectuating
10 a contact with contact points 232 and 234. Examples of materials that may be used for gel cap 330 include elastomers and foam.

 Among advantages provided by gel cap 330, users can more readily use fingers to actuate contact points 232 and 234. The gel cap 330 has a tactile feedback that allows users to make incremental adjustments to the position of the gel cap's mass within recess 130. The
15 gel cap 330 can be gripped with a sustained contact and moved to contact points 232, 234 as desired. Furthermore, the motion required by the user is lateral, to enable contact points 232 and 234 of recess 130 to be actuated when, for example, the user's arm is extended while placing a thumb on the gel cap 330 to enter input.

 FIG. 5 illustrates a gel filler 420 combined with a moveable surface 430 on recess
20 130. The gel filler 420 is formed from a sealed gelled mass that is fixed to recess 130 at bottom position 335. The moveable surface 430 is mounted over the gel filler 420. The moveable surface 430 may be fixed to an exterior surface 422 of gel filler 420. The mass of the gel filler 420 may be moved within recess 130 when moveable surface 430 is directed in

one direction or another. The moveable surface 430 is moved to displace the interior mass of gel filler 420, so as to apply pressure or cause contact for actuating contact points 232 and 234.

FIG. 6 illustrates a moveable surface 530 mounted over gel filler 420, under another embodiment of the invention. The moveable surface 530 includes an extension 532 extending from a base 535. The extension 532 facilitates finger contact by a user to displace mass within gel fill 420, so as to enable base 535 to make contact with contact points 232 and 234.

FIG. 7 illustrates another embodiment illustrating a contact-sensitive surface feature shaped as a protrusion 620. The protrusion 620 may include multiple contact points 622, 624. The contact points 622, 624 may be positioned to indicate a function to the user. For example, first contact point 622 may direct the contact towards the display surface 122 (FIG. 1) of electronic device 100 to indicate an upward navigation or scroll for the display surface 122. Likewise, a second contact point 624 may direct away from display surface 122 to indicate navigation or scrolling in an opposite direction.

Shapes other than recesses and protrusions illustrated by FIGS. 1-7 are under different embodiments of the invention. The conductive section 224 may be formed into a variety of shapes to create an input mechanism that facilitates use of electronic device 100.

D. Other Embodiments

While other embodiments described herein provide for a shaped contact-sensitive feature, another embodiment may incorporate three-dimensional contact-sensitive effect on a surface of the housing 110 for the electronic device 100. FIG. 8 is a cross-sectional view illustrating a surface mounted gel volume 730 on display surface 722, formed as an exterior to a first layer 710. The first layer 710 is substantially planar, and forms a portion of a

contact-sensitive display module 720. The gel volume 730 may be fixed to the surface of front panel 112. A moveable component 735 is mounted over the gel volume 730. The moveable component 735 can be directed to displace the interior mass of gel volume 730 so as to cause contact with one or more contact points 722 on the underside of the gel volume 730. For example, the combination of moveable component 735 on gel volume 730 can be operated similar to a button if moveable component 725 is directed towards surface 710.

Alternatively, the combination of the moveable component 735 and gel volume 730 can be operated as a navigation or swivel input mechanism. This may be accomplished by distributing a plurality of contact points on surface 710 in position to be contacted or pressured by movement of moveable component 735.

Structures similar to input mechanisms such as described with recesses 130 and 132 (FIG. 1) may alternatively be employed as sensor mechanisms. In one embodiment, housing 110 (FIG. 1) may be lined with a layer formed from contact-sensitive material, such as ELECTRODAG. At certain regions on housing 110, the contact-sensitive lining may be made to act as sensors that detect contact by a user's hand. The electronic device 100 may be configured based on the sensors detecting the hand or other component. As an example, sensors on a backside of housing 110 may detect whether a user is employing a left hand or right hand to hold the electronic device. The operations of the electronic device 100 may then be configured for left-handed or right-handed users, as detected by the sensors.

E. Hardware Components

FIG. 9 is a block diagram of electronic device 100, including components for receiving input from the contact-sensitive surface or feature shown with FIGS. 1-8.

According to an embodiment, electronic device 100 includes a processor 840 coupled to a

first memory 844 and a second memory 846. The processor 840 is coupled to a display driver 822. The processor 840 combines with display driver 822 to process and signal data for presentation on a module display 820. A digitizer 830 is coupled to processor 840 via an analog-digital (AD) converter 832. The AD converter 832 is coupled to substrate 228 (FIG.

2) to receive voltage differential signals generated through deflection of conductive section 224 (FIG. 2). In an embodiment, AD converter 832 includes first channel 833 and second channel 837 to receive voltage differential signals and generate a corresponding digital signal for processor 840.

The electronic device 100 may include one or more expansion slots. In an embodiment shown, a first peripheral port 802 enables one or more types of accessory devices to be connected to processor 840. In addition, electronic device 100 may include a wireless peripheral port 804 that enables information to be communicated to processor 840 from an external source. The wireless peripheral port 804 forwards incoming communications to an amplifier 806 for processor 840. A second processor 808 intercepts communications incoming to and/or outgoing from wireless peripheral port 804 for purpose of facilitating conversion of data signals between formats and protocols of wireless communications, and those that can be processed by processor 840.

The display module 820 cooperates with display driver 822 to display images on display surface 822. The first memory 844 may be non-volatile. The processor 840 combines with display driver 822 to present the data in a paginated format on display module 820.

F. Conclusion

In the foregoing specification, the invention has been described with reference to specific embodiments thereof. It will, however, be evident that various modifications and
